Troubleshoot

DNS Server Outage:

VM has long load times on browsers such as google chrome along with returning "server IP address cannot be found". Nothing has been changed or updated within the VM system. A possible theory is there is a DNS server outage which is causing IP transport to fail for domain names. To verify, Windows Run dialog box is opened, and the command "nslookup" is used which responds with "DNS request timed out". Windows event viewer also shows an error involving the DHCP where an address was not provided. Both tools confirm the theory that there is a DNS server outage. A plan of action where Windows control plan will be used to manually configure the DNS which will be done immediately as it directly impacts work. The solution is implemented by going through Windows control panel, Network and Internet, Network and Sharing center, and Change Adapter Settings. Through here, the Ethernet properties are opened, and Ivp4 properties are changed through the preferred DNS server turning it into. The issue is fixed, and there is full system functionality as "nslookup" returns the new DNS, and a browser tab loads in quickly. For further issues with retrieving domain names, Windows control panel must be used to manually change DNS settings.
